

Socrates' Example

- Socrates is a man and all men are mortal
Therefore Socrates is mortal
- Initial state
 - 1) $\text{is_man}(\text{socrates})$
 - 2) $\neg \text{is_man}(X) \vee \text{is_mortal}(X)$
 - 3) $\neg \text{is_mortal}(\text{socrates})$ (negation of theorem)
- Resolving (1) & (2) gives new state
 - (1)-(3) & 4) $\text{is_mortal}(\text{socrates})$

Aristotle's Example: Search Space

Resolution Proof Tree (Proof 1)

Resolution Proof Tree (Proof 2)

You said that all men were mortal. That means that for all things X , either X is not a man, or X is mortal. If we assume that Socrates is not mortal, then, given your previous statement, this means Socrates is not a man. But you said that Socrates *is* a man, which means that our assumption was false, so Socrates must be mortal.

Example: KB

Jack owns a dog.
Every dog owner is an animal lover.
No animal lover kills an animal.
Either Jack or Curiosity killed the cat, who is named Tuna.
Did Curiosity kill the cat?

Example: KB

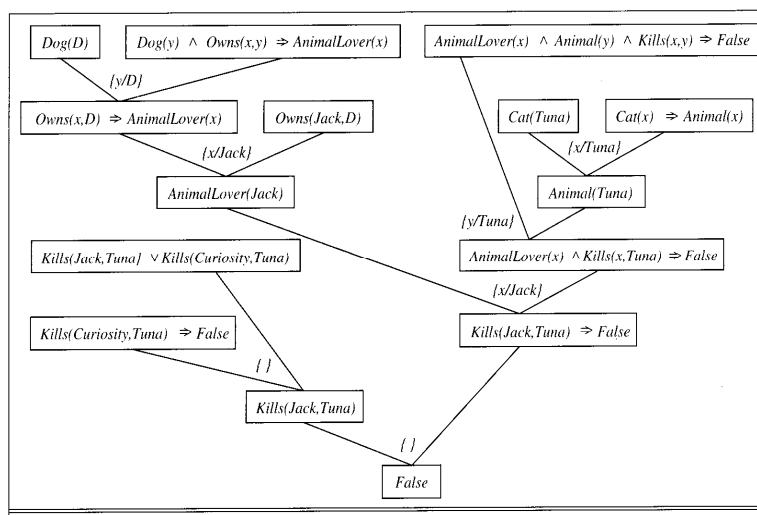

Jack owns a dog.
Every dog owner is an animal lover.
No animal lover kills an animal.
Either Jack or Curiosity killed the cat, who is named Tuna.
Did Curiosity kill the cat?

- A. $\exists x \text{ Dog}(x) \wedge \text{Owns}(\text{Jack}, x)$
- B. $\forall x (\exists y \text{ Dog}(y) \wedge \text{Owns}(x, y)) \Rightarrow \text{AnimalLover}(x)$
- C. $\forall x \text{ AnimalLover}(x) \Rightarrow \forall y \text{ Animal}(y) \Rightarrow \neg \text{Kills}(x, y)$
- D. $\text{Kills}(\text{Jack}, \text{Tuna}) \vee \text{Kills}(\text{Curiosity}, \text{Tuna})$
- E. $\text{Cat}(\text{Tuna})$
- F. $\forall x \text{ Cat}(x) \Rightarrow \text{Animal}(x)$

Example: (CNF)

- A1. $Dog(D)$
- A2. $Owns(Jack, D)$
- B. $Dog(y) \wedge Owns(x, y) \Rightarrow AnimalLover(x)$
- C. $AnimalLover(x) \wedge Animal(y) \wedge Kills(x, y) \Rightarrow False$
- D. $Kills(Jack, Tuna) \vee Kills(Curiosity, Tuna)$
- E. $Cat(Tuna)$
- F. $Cat(x) \Rightarrow Animal(x)$

Example: Proof Tree

Reduction to propositional inference

Suppose the KB contains just the following:

$\forall x \text{ King}(x) \wedge \text{Greedy}(x) \Rightarrow \text{Evil}(x)$

$\text{King}(\text{John})$

$\text{Greedy}(\text{John})$

$\text{Brother}(\text{Richard}, \text{John})$

- Instantiating the universal sentence in **all possible** ways, we have:

$\text{King}(\text{John}) \wedge \text{Greedy}(\text{John}) \Rightarrow \text{Evil}(\text{John})$

$\text{King}(\text{Richard}) \wedge \text{Greedy}(\text{Richard}) \Rightarrow \text{Evil}(\text{Richard})$

$\text{King}(\text{John})$

$\text{Greedy}(\text{John})$

$\text{Brother}(\text{Richard}, \text{John})$

- The new KB is **propositionalized**: proposition symbols are
- $\text{King}(\text{John})$, $\text{Greedy}(\text{John})$, $\text{Evil}(\text{John})$, $\text{King}(\text{Richard})$, etc.

Reduction to propositional inference

- Every FOL KB can be propositionalized so as to preserve entailment (A ground sentence is entailed by new KB iff entailed by original KB)
- Idea: propositionalize KB and query, apply resolution in PC, return result
- Problem: with function symbols, there are infinitely many ground terms,
 - e.g., $\text{Father}(\text{Father}(\text{Father}(\text{John})))$

Reduction to propositional inference

Theorem: Herbrand (1930). If a sentence α is entailed by a FOL KB, it is entailed by a **finite** subset of the propositionalized KB

Problem: works if α is entailed, loops if α is not entailed

Theorem: Turing (1936), Church (1936) Entailment for FOL is **semidecidable** (algorithms exist that say yes to every entailed sentence, but no algorithm exists that also says no to every nonentailed sentence.)

Problems with propositionalization

- Propositionalization seems to generate lots of **irrelevant** sentences.
- E.g., from:
 - $\forall x \text{ King}(x) \wedge \text{Greedy}(x) \Rightarrow \text{Evil}(x)$
King(John)
 $\forall y \text{ Greedy}(y)$
Brother(Richard, John)
 - it seems obvious that *Evil(John)*, but propositionalization produces lots of facts such as *Greedy(Richard)* that are irrelevant

Generalized Modus Ponens (GMP)

$$\frac{p_1', p_2', \dots, p_n', (p_1 \wedge p_2 \wedge \dots \wedge p_n \Rightarrow q)}{q\theta}$$

p_1' is *King(John)* p_1 is *King(x)*

p_2' is *Greedy(y)* p_2 is *Greedy(x)*

θ is $\{x/\text{John}, y/\text{John}\}$ q is *Evil(x)*

$q\theta$ is *Evil(John)*

Soundness and Completeness of GMP

- GMP is sound
 - Only derives sentences that are logically entailed (proof on p276 in text)
- GMP is complete for a KB consisting of definite clauses
 - Complete: derives all sentences that are entailed
 - OR...answers every query whose answers are entailed by such a KB
 - **Definite clause**: disjunction of literals of which exactly one is positive,
 - e.g., $\text{King}(x) \text{ AND } \text{Greedy}(x) \rightarrow \text{Evil}(x)$
 $\text{NOT}(\text{King}(x)) \text{ OR } \text{NOT}(\text{Greedy}(x)) \text{ OR } \text{Evil}(x)$

Forward chaining

- FC: “Idea” fire any rule whose premises are satisfied in the *KB*, add its conclusion to the *KB*, until query is found
- Deduce new facts from axioms
- Hopefully end up deducing the theorem statement
- ❖ Can take a long time: not using the goal to direct search
- Sound and complete for first-order definite clauses
- Datalog = first-order definite clauses + no functions
- FC terminates for Datalog in finite number of iterations
- May not terminate in general if α is not entailed
- This is unavoidable: entailment with definite clauses is semidecidable

Forward chaining algorithm

```
function FOL-FC-ASK(KB,  $\alpha$ ) returns a substitution or false
  repeat until new is empty
    new  $\leftarrow \{ \}$ 
    for each sentence r in KB do
       $(p_1 \wedge \dots \wedge p_n \Rightarrow q) \leftarrow \text{STANDARDIZE-APART}(r)$ 
      for each  $\theta$  such that  $(p_1 \wedge \dots \wedge p_n)\theta = (p'_1 \wedge \dots \wedge p'_n)\theta$ 
        for some  $p'_1, \dots, p'_n$  in KB
           $q' \leftarrow \text{SUBST}(\theta, q)$ 
          if  $q'$  is not a renaming of a sentence already in KB or new then do
            add  $q'$  to new
             $\phi \leftarrow \text{UNIFY}(q', \alpha)$ 
            if  $\phi$  is not fail then return  $\phi$ 
    add new to KB
  return false
```

Backward chaining

- BC: “Idea” work backwards from the query q in $(p \rightarrow q)$
 - check if q is already known, or
 - prove by BC all premises of some rule concluding q
- Start with the conclusion and work backwards
 - Hope to end up at the facts from KB
- Widely used for [logic programming](#)
- PROLOG is backward chaining

Remarks:

Avoid loops: check if new subgoal is already on the goal stack

Avoid repeated work: check if new subgoal has already been proved true, or has already failed

Backward chaining algorithm

```
function FOL-BC-ASK( $KB, goals, \theta$ ) returns a set of substitutions
  inputs:  $KB$ , a knowledge base
          $goals$ , a list of conjuncts forming a query
          $\theta$ , the current substitution, initially the empty substitution  $\{ \}$ 
  local variables:  $ans$ , a set of substitutions, initially empty
  if  $goals$  is empty then return  $\{ \theta \}$ 
   $q' \leftarrow SUBST(\theta, FIRST(goals))$ 
  for each  $r$  in  $KB$  where  $STANDARDIZE-APART(r) = (p_1 \wedge \dots \wedge p_n \Rightarrow q)$ 
    and  $\theta' \leftarrow UNIFY(q, q')$  succeeds
       $ans \leftarrow FOL-BC-ASK(KB, [p_1, \dots, p_n | REST(goals)], COMPOSE(\theta, \theta')) \cup ans$ 
  return  $ans$ 
```

$$SUBST(COMPOSE(\theta_1, \theta_2), p) = SUBST(\theta_2, SUBST(\theta_1, p))$$
