SUMMARY: Yeasts were isolated from 16 out of 60 milk samples (26.66%) collected from lactating Friesian cows. 9 of the isolates were identified as Cryptococcus neoformans. The remaining isolates were Cr. albidos (1), Torulopsis spherica (2), T. species (1) and Rhodotorula species (3).

INTRODUCTION

Cryptococcus neoformans is the most common yeast causing severe bovine mastitis in a subacute or chronic form with subsequent serious economic losses. The first signs of infection are severe swelling and firmness of the udder and enlargement of the regional lymph nodes. In most cases, the milk yield is markedly reduced and the milk is visibly abnormal (Buxton and Fraser, 1977). This type of yeast is encapsulated, non spor-forming organism that is highly resistant to antibiotics. Cases with elevated systemic temperature and anorexia are not uncommon (Bruce and Larson, 1985).

Cryptococcus neoformans as a cause of bovine mastitis has been the subject of extensive studies. It was isolated from different outbreaks of mastitis in cattle by Carter and Young (1950); Stuart (1951); Pounden et al. (1952); Innes et al. (1952); Emmons (1952); Simmon et al. (1953); Galli (1954); Kauker (1955); Charlie (1955); de Gracia (1959); Funke (1960); Scholer et al. (1961); Mehnert et al. (1964); Bertschinger et al. (1964); Parisia (1965); Monga et al. (1970); Monga and Kalra (1971) and Spika and Petrovic (1976).

In Egypt, Cr. neoformans was isolated from 2 goats (Abdallah, 1969) and one cow (Abdel Ghani et al., 1978) suffering from mastitis. The aim of this work was to study the role of Cr. neoformans as a cause of mastitis in cows in Egypt.

CRYPTOCOCCUS NEOFORMANS AS A CAUSE OF BOVINE

MATERIALS AND METHODS

Sixty milk samples were collected from lactating Friesian cows in a dairy farm suffering from mastitis. The mammary glands were hard, hot and swollen. The milk samples were greyish-white in colour; some samples had clots, flakes and were watery while others looked normal.

The milk samples were collected in sterile screw-capped bottles and centrifuged at 3000 rpm for 15 minutes. The supernatant was decanted and the sediment was cultured on Sabouraud’s dextrose agar slant and incubated at 25°C for 48-96 hours. The yeast colonies were examined macroscopically and microscopically.

Identification was done by fermentation and assimilation of glucose, galactose, maltose, sucrose, inositol and dulcitol, nitrate assimilation hydrolysis of urea and retention of Trypan blue on My 10/20 agar for 7 days at 22-25°C. Demonstration of capsules was carried out by inoculating 48 hours culture on Sabouraud’s dextrose agar, suspended in sterile physiological saline, in amounts of 0.2-0.3 ml intramuscularly in the thigh of white swiss mice. Fresh smears were prepared after 12-24 hours from the site of injection and mixed with India ink, spread on a slide, covered with a cover slip and examined under the microscope.

RESULTS

Yeasts were isolated from 16 out of 60 milk samples (26.66%). Identification of positive isolates by fermentation and assimilation was done on the basis of the table published by (Leanor and Carey, 1979).

As shown in Table 1, Cryptococcus isolates were recovered from 10 samples (16.6%). 9 isolates were identified as Cr. neoformans and one as Cr. albidos.

Torulopsis species could be isolated only from 3 cases (5%). Two isolates were identified as Torulopsis spherica and the other one was Torulopsis species. The remaining 3 isolates were identified as Rhodotorula species (5%). All Cr. neoformans isolates showed a clear capsule when mixed with India ink (Fig. 1).

DISCUSSION

Isolation of Cr. neoformans from milk of lactating Friesian cows can be considered as an important finding. Although this yeast has been isolated from pigeon droppings in different parts of Egypt (Refai et al., 1983) and from droppings of rats, chicken and soil in various poultry farms (Refai and Kotb unpublished data) it has been rarely recovered from animals. It seems that native breeds of cattle and buffaloes are probably less susceptible than Friesian cows. In the present work yeasts were recovered from 16 out of 60 Friesian cows (26.66%) and Cr. neoformans alone was isolated from 9 cows (15%). The milk samples from which Cr. neoformans was isolated appeared normal. As this milk may be consumed unpasteurized or used for manufacturing of cheese or youghurt, infection of consumers would be a high possibility. Yossef and Refai (1986) have reported 4 cases of fatal Cryptococcosis in man. However, the source of infection in those cases was obscure.

This study should draw the attention to the possible role of animals and birds in transmitting Cr. neoformans to man which in fact needs further extensive studies.
