Abstract

The study investigated whether dietary methionine (Met) affects egg weight and antioxidant status through regulating gene expression of ovalbumin (*OVAL*), nuclear factor erythroid 2 like 2 (*Nrf2*) and haem oxygenase 1 (*HO-1*) in laying duck breeders. Longyan duck breeders (n 540, 19 weeks) were randomly assigned to six treatments with six replicates of fifteen birds each. Breeders were fed diets with six Met levels (2.00, 2.75, 3.50, 4.25, 5.00 and 5.75 g/kg) for 24 weeks. The egg weight (g), egg mass (g/d), feed conversion ratio, hatchability, 1-d duckling weight, albumen weight, albumen proportion and *OVAL* mRNA level improved with dietary Met levels, whereas yolk proportion decreased ($P < 0.05$). The weight of total large yellow follicles increased linearly ($P < 0.001$) and quadratically ($P < 0.05$) with dietary Met concentration, and their weight relative to ovarian weight showed a linear ($P < 0.05$) effect. Dietary Met level had a linear ($P < 0.05$) and quadratic ($P < 0.001$) effect on the gene expression of glutathione peroxidase (*GPX1*), *HO-1* and *Nrf2*, and quadratically ($P < 0.05$) increased contents of GPX and total antioxidant capacity (T-AOC) in liver of duck breeders. In addition, maternal dietary Met enhanced gene expression of *GPX1*, *HO-1* and *Nrf2*, increased contents of GPX and T-AOC and reduced carbonylated protein in the brains of hatchlings. Overall, dietary Met concentration affected egg weight and albumen weight in laying duck breeders, which was partly due to gene expression of *OVAL* in oviduct magnum. A diet containing 4.0 g Met/kg would achieve optimal hepatic *GPX1* and *Nrf2* expression, maximise the activity of GPX and minimise lipid peroxidation.

Key words: Methionine: Antioxidant capacity: Ovalbumin: Performances: Laying duck breeders

Methionine (Met) is considered to be the highest priority amino acid in poultry diets as it is the first limiting amino acid and has multiple biological functions in avian species⁽¹⁾. Dietary Met levels affect the secretion of hormones in animals, such as triiodothyronine, insulin growth factor-II, estradiol, follicle-stimulating hormone and luteinising hormone^(2–4). In avian species, Met deficiency impairs the laying performance, egg mass, feed conversion ratio (FCR)^(5–7), antibody production⁽⁸⁾ and retards female reproductive organ development^(9–11), including relative weight of the ovary, oviduct length, total number of follicles, large and small, and the growth rate of

secondary follicles⁽⁴⁾. Met deficiency can lead to imbalanced lipid and protein metabolism, which reduces egg quality and increases the incidence of reproductive problems associated with fatty liver and obesity^(10–13). The Met is involved in the biosynthesis of GSH, cysteine, taurine and carnitine⁽¹⁴⁾, which play vital roles as antioxidants^(15–17). Several studies have reported that dietary Met supplementation increased the content of cysteine, taurine and the activities of antioxidant enzymes, and reduced the lipid peroxidation in Chinese broiler breeders and commercial broiler chickens^(5,18). However, it was reported that dietary Met levels ranging from 2.5 to 5.0 g/kg did

Abbreviations: cDNA, complementary DNA; FCR, feed conversion ratio; GPX, glutathione peroxidase; HO-1, haem oxygenase 1; LYF, large yellow follicles; MDA, malondialdehyde; Met, methionine; Nrf2, nuclear factor erythroid 2 like 2; *OVAL*, ovalbumin; SYF, small yellow follicles; T-AOC, total antioxidant capacity; T-SOD, total superoxide dismutase.

not affect the plasma glutathione redox system in laying ducks, which was possibly due to not low enough Met level in the basal diet⁽⁷⁾. In this regard, it was hypothesised that a control diet containing less Met (2.0 g *v.* 2.5 Met/kg) might affect the activities of antioxidant enzymes and their mRNA expression levels in duck breeders and their offspring by modulating the expression of nuclear factor erythroid 2 like 2 (*Nrf2*), but this has not been investigated previously. Moreover, previous reports have shown that dietary Met levels increases the egg weight and albumen secretion in different strains of laying ducks and laying hens, which was reflected in egg weight^(3,6,7), but the relationship between them was little referred. Thus, it might be possible that dietary Met can induce the same effect in duck breeders as laying ducks, which may lead to an increase in the weight of hatchings, by altering gene expression of ovalbumin (*OVAL*, the dominant protein in albumen) in duck breeders.

In poultry, Met improves the productivity, reproductive performance, egg quality, antioxidant defence system and humoral and cellular immune responses, and attenuates the adverse impacts of non-optimal temperature (cold or heat stress)^(5,7,18,19). Thus, the effects of Met on commercial and local strains of broiler breeders, laying hens, quails, turkeys, meat-type and egg-type ducks can be positive, but variable^(3,6,7,18,20,21). Further, few studies have reported the effect of dietary Met levels in laying duck breeders. The Longyan duck breeders are the most popular laying ducks for duckling production in South China, mainly because of their high productivity, adaption to high ambient temperature and resistance to diseases. Therefore, the current study sought to determine the effect of dietary Met levels on productivity, reproductive performance, antioxidant capacity, *OVAL* and antioxidant-related gene expression in laying duck breeders; it also examined whether dietary Met increases the secretion of albumen by upregulating expression of the *OVAL* gene in duck breeders and improving the activities of antioxidant enzymes and their gene expression levels in duck breeders and their offspring by modulating the expression of *Nrf2*.

Methods

Birds, diets and experimental design

All experimental procedures were approved by the Animal Care and Use Committee of Guangdong Academy of Agriculture Sciences, China. A total of 540 female Longyan laying duck breeders with the same genetic background in terms of the parental generation and with comparable body weight (BW) at 19 weeks of age were randomly assigned to six dietary treatments, each comprising six replicates of fifteen birds. The ducks were individually housed in galvanised steel battery cages (length 42 cm × width 30 cm × height 50 cm; Guangzhou Huanan Poultry Equipment Co., Ltd) with a nipple drinker and feeder; the ambient temperature varied from 15 to 32°C during the 24-week experimental period. Fresh drinking water was available *ad libitum*, and 80 g of feed per duck in pellet form was introduced twice daily at 07.00 and 15.00 hours. A 16 h light–8 h dark photoperiod was applied throughout the study.

The basal diet (Table 1) was formulated to satisfy the nutritional requirements for Longyan laying duck breeders with the exception of Met. The six groups were fed the basal diet supplemented with 0 (control), 0.75, 1.50, 2.25, 3.00 or 3.75 g Met/kg in the form of DL-Met (MetAMINO[®]; Evonik Industries AG), respectively, which resulted in total contents of 2.00, 2.75, 3.50, 4.25, 5.00 and 5.75 g/kg. Male Longyan duck breeders were fed a standard commercial diet containing 10.87 MJ/kg metabolisable energy/kg, 170 g/kg crude protein, 8.00 g/kg Ca, 3.80 g/kg available phosphorus and 4.50 g/kg Met. At 38 weeks of age, each breeder was artificially inseminated twice weekly with 100 µl of pooled semen⁽²²⁾ to evaluate reproductive performance (fertility, hatchability and proportion of healthy ducklings). In total, 1800 eggs (fifty eggs from each replicate) were collected over 5 sequential days between 38 and 39 weeks from the 2nd day after the first artificial insemination, the eggs were weighed, labelled and stored in a dark controlled-temperature room (18°C and 75 to 80% relative humidity), and then incubated in the incubator (JXB2000; Dezhou Jingxiang Technology Co., Ltd) for 28 d. On the first 5 d, the incubator temperature was 38.4°C with 45% humidity; from 6 to 10 d, the temperature was 38.0°C with 50% humidity; from 11 to 15 d, the temperature was 37.5°C with 50% humidity; from 16 to 20 d, the temperature was 37.1°C with 55% humidity; from 21 to 25 d, the temperature was 36.8°C with 60% humidity; and from 26 to 28 d, the temperature was 36.5°C with 65% humidity. The eggs were candled on days 6 and 18 to eliminate infertile eggs and dead embryos. The fertility and hatchability were

determined along with hatchling weights of ducklings being recorded on the hatching day.

Sample collection

At the end of the experiment (after feeding for 24 weeks), twelve breeders per treatment were selected at random (excluding obvious outliers in terms of BW, two breeders in each replicate) for sampling. Heparinised blood was collected from the wing vein, centrifuged at 1000 **g** for 20 min at 4°C and the plasma was then collected and stored at -20°C until further analysis. The breeders were then stunned, exsanguinated and the ovaries were collected and weighed. Samples were collected from the liver, oviduct magnum and ovaries^(23,24), which were rinsed rapidly with PBS, snap-frozen in liquid N₂ and stored at -80°C. After hatching, twelve ducklings from each treatment group (two ducklings from each replicate) were stunned, exsanguinated and samples of the liver and brain⁽²⁵⁾ were harvested, rinsed quickly with PBS, snap-frozen in liquid N₂ and stored at -80°C.

Determination of productive and reproductive performance

The feed intake was recorded daily on a per replicate basis. The numbers of total, broken and shell-less eggs were recorded daily by replicate. The eggs produced were individually weighed and graded daily. Egg production (%) (100 × number of eggs/number of breeders), egg weight (g), egg mass (g/d), average daily feed intake and FCR (g feed/g egg) were calculated daily, on a per replicate basis, and the data were then pooled before analysis. The fertility and hatchability were also calculated, and the proportion of healthy ducklings was calculated as the number that were clean, dry, free of deformities and with bright eyes, as described by Tona *et al.*⁽²⁶⁾, expressed as a percentage relative to the total number of hatchlings.

Egg quality

At the end of the experiment, four eggs were collected at random (excluding obvious outliers such as excessively large or small, rough, misshapen, cracked) from each replicate, and the average of these twenty-four eggs was calculated per treatment to determine the quality traits. Yolk colour score, albumen height and Haugh unit (albumen quality) were measured on the day of collection using an Egg Analyzer (model EA-01; ORKA Food Technology). The strength of the shell was determined on the vertical axis using an Egg Force Reader (model EFR-01; ORKA Food Technology). Eggshell thickness was measured using a digital micrometre, and egg shape index (SI) was determined with a digital caliper and calculated as $SI = \text{width} \times 100 / \text{length}$, where the length was the distance between the blunt and pointed ends and the width was the diameter at the mid-length. The eggs were weighed, and then the yolks were separated, weighed and expressed as percentages of egg weight. The shells with membranes were weighed after drying at 105°C and expressed as percentages of egg weight. Finally, the albumen weight was calculated as egg weight minus the weight of yolk and eggshell, and expressed as percentages of egg weight.

Ovary and oviduct-related indices

The collected ovaries, small yellow follicles (SYF; 3 mm < diameter < 8 mm), large yellow follicles (LYF; diameter ≥ 8 mm) and oviduct were weighed using an electronic balance (AB-S/PH; Mettler Toledo). The numbers of total SYF and LYF were recorded. The weights of total SYF and LYF were calculated relative to the ovarian weight and expressed as ratios.

Biochemical assay of plasma and tissue samples

The plasma contents of GSH and malondialdehyde (MDA), activities of total superoxide dismutase (T-SOD) and glutathione peroxidase (GPX), and the total antioxidant capacity (T-AOC) were determined in duplicate colourimetrically using commercial kits according to the manufacturer's protocols (Jiancheng Bioengineering Institute), similar to that described by Huang *et al.*⁽²⁷⁾.

A quantity of 40 mg of frozen liver or brain were homogenised on ice in 4 ml of homogenisation buffer (0.05 M TRIS-HCl, pH 7.4, 1 mM EDTA, 0.25 M sucrose) with an Ultra-Turrax (T8; IKA) for 5 s at 3000 **g**. The homogenate was centrifuged at 12 000 **g** for 10 min at 4°C, and the supernatant was stored at -80°C. The concentrations of GSH, MDA and activities of T-SOD, GPX and T-AOC in the livers of breeders, as well as in the livers and brains of ducklings, were measured with kits (Jiancheng Bioengineering Institute). The concentrations of protein carbonyl (PC) in the brains of ducklings were measured with kits (Jiancheng Bioengineering Institute), similar to that described by Huang *et al.*⁽²⁷⁾. All samples were measured in duplicate at appropriate dilutions in order to determine the concentrations of GSH, MDA, PC and activities of the enzymes in the linear range for standard curves constructed with pure enzymes. The protein contents of supernatants were determined using Coomassie Brilliant Blue G250 (Sigma Chemical) with bovine serum albumin as the standard.

Total RNA extraction and reverse transcription

Total RNA was extracted from the frozen tissues using TRIzol[®] (Invitrogen) and treated with DNase (Takara) according to the manufacturers' protocols. RNA concentrations were determined by NanoDrop 1000 (ThermoFisher Scientific) and RNA integrity was verified by electrophoresis on 1% agarose gels.

Total RNA (2.5 µg) from each sample was used to generate complementary DNA (cDNA) in a final volume of 20 µL according to the manufacturer's instructions (Promega). The cDNA was then diluted 1:10 with nuclease-free water (Ambion) and stored at -20°C until use. Primers for the genes of interest were designed with Primer Premier 5.0 based on duck sequences in GenBank, as shown in Table 2; they were obtained from Shanghai ShengGong Biological Company. The cDNA was amplified by PCR under the optimal conditions, which consisted of an initial 5-min denaturation at 95°C; thirty-five cycles of 30 s at 95°C, 30 s at the annealing temperature (Ta) and extension for 30 s at 72°C; and a final extension at 72°C for 10 min. Aliquots of PCR products were evaluated by electrophoresis in 1.5% agarose gels and excised products from the gels were sequenced to verify authenticity.

Ta, annealing temperature; *SOD1*, superoxide dismutase 1; *GPX1*, glutathione peroxidase 1; *CAT*, catalase; *HO-1*, haem oxygenase 1; *Nrf2*, nuclear factor erythroid 2 like 2; *OVAL*, ovalbumin.

Quantitative real-time PCR analysis

Quantitative real-time PCR was performed using the same primers to quantify mRNA contents. Each 20 µl PCR mixture contained 10 µl of 2X iQTM SYBR Green Supermix, 0.8 µl (10 mM) of each primer and 2 µl of cDNA. The mixtures were incubated using an iCycler iQ Real-time Detection system (Bio-Rad) for thirty-nine cycles (95°C for 15 s and at the Ta for 30 s). Quantification of the transcripts was performed using a standard curve with 10-fold serial dilutions of cDNA. A melting curve was constructed to verify that only a single PCR product was amplified. Samples were assayed in triplicate with standard deviations of threshold cycle (C_t) values not exceeding 0.5. The $2^{-\Delta\Delta C_t}$ method was used with β -actin as the reference transcript for relative gene expression and then expressed relative to the transcript abundance in birds fed the control diet⁽²⁸⁾.

Statistical analysis

Replicate (n 6) served as the experimental unit, where two breeders and ducklings were sampled per replicate unless stated otherwise. The experimental data were analysed by one-way ANOVA using the general linear model procedure in SAS (version 9.2; SAS Institute Inc.). Differences between means were assessed using Duncan's multiple range tests at $P < 0.05$ probability level. Results are expressed as means with their standard errors, derived from the ANOVA error mean square. Only when the main effect was shown to be significant ($P < 0.05$), orthogonal comparisons were used to estimate the linear and quadratic effects of Met supplementation. Quadratic regressions ($Y = c + bX + aX^2$) were fitted to the responses of the dependent variables to Met supplementation. The dietary concentration of Met at which the response first reached 95% of the maximum was used to estimate the requirement⁽²⁹⁾.

The sample size (n) was estimated using the following equation: $n = \psi^2 (\sum (S_i^2) / K) / \left[\sum (X_{i \text{ average}} - X_{\text{average}})^2 / (K - 1) \right]^{(30)}$, where n is the sample size, ψ is ψ value, K is the group count, α is the probability of a type I error occurring at 5%, β is the probability of

a type II error occurring at 10%, S_i and $X_{i \text{ average}}$ are the standard deviation and the average value of corresponding i th group, respectively. For example, for the most variable index, $\psi = 3.08$, $\alpha = 0.05$, $\beta = 0.10$, $X_{\text{average}} = 2.00$ and the sample size needed to detect a significant main effect between groups was at least n 6 ducks per group.

Results

Productive and reproductive performance

Dietary Met significantly affected ($P < 0.05$) the egg weight, egg mass, FCR, hatchability, healthy ducklings and weight of hatchlings (Table 3). The egg weight and 1 d duckling weight increased in a linear ($P < 0.001$) manner, with a lesser quadratic ($P < 0.05$) component as Met concentration increased. The egg mass increased, and then decreased quadratically ($P < 0.05$) as dietary Met concentration increased. The hatchability and proportion of healthy ducklings increased in a linear ($P < 0.05$) and quadratic ($P < 0.05$) manner as Met concentration increased. There were no significant effects ($P > 0.05$) of dietary Met levels on daily egg production and fertility.

Egg quality

Among the egg quality indices (Table 4), the albumen weight, albumen proportion and Haugh unit increased in a linear ($P < 0.05$) and quadratic ($P < 0.05$) manner with dietary Met concentration, whereas the yolk proportion decreased in a linear ($P < 0.001$) and quadratic ($P < 0.05$) manner. There were no significant effects ($P > 0.05$) of increasing Met on the eggshell thickness, egg SI, eggshell strength, yolk colour and eggshell weight and proportion.

Ovary and oviduct-related indices

As shown in Table 5, the weight of total LYF increased linearly ($P < 0.001$) with a minor quadratic effect ($P < 0.05$), and the ratio of total LYF weight/ovarian weight was also affected in a linear ($P = 0.002$) manner by dietary Met concentration. The

as dietary Met concentration increased; hepatic content of MDA showed reciprocal changes, with only a trend towards a quadratic ($P = 0.062$) effect. Dietary Met levels increased the hepatic expression of *GPX1* in a linear ($P < 0.05$) and quadratic ($P < 0.001$) manner in laying duck breeders, and the expression of catalase (*CAT*) changed linearly ($P < 0.001$) with the Met levels in diet. There was a linear ($P < 0.01$) and quadratic ($P < 0.01$) effect of dietary Met levels on the hepatic expression of haem oxygenase 1 (*HO-1*), whereas *Nrf2* changed quadratically ($P < 0.001$) with dietary Met levels (Table 7). There were no significant effects ($P > 0.05$) on the plasma contents of GSH or MDA, nor on the activities of T-SOD, GPX or T-AOC (data not shown).

Ovalbumin gene expression in the oviduct magnum of duck breeders

There was an obvious linear ($P < 0.001$) and quadratic ($P < 0.001$) effect of dietary Met on the relative abundance of OVAL transcripts in the oviduct magnum (Table 7).

Antioxidative indices and related genes expression in the liver and brain of hatchlings

As shown in Table 8, the cerebral but not hepatic activities of T-SOD, GPX and T-AOC in newly hatched ducklings increased quadratically ($P < 0.01$) as Met content of the breeders' diet increased; reciprocal quadratic ($P < 0.05$) changes in PC were evident. There were no effects on GSH or MDA contents of either tissue. Dietary Met for the breeders had quadratic ($P < 0.05$) effects on the cerebral expression of *GPX1*, *HO-1* and *Nrf2* and hepatic expression of *HO-1* in the hatchlings (Table 9).

Estimations of the dietary methionine requirements of laying duck breeders

Results of dietary Met requirements of laying duck breeders as estimated by the quadratic regression analysis are shown in Table 10. The dietary Met requirements for Longyan duck breeders from 19 to 43 weeks of age for optimising egg weight, albumen weight, egg mass, FCR, hatchability, maximal expression of hepatic *GPX1* and *Nrf2* and its activities were 4.6, 4.9, 4.4, 4.8, 4.0, 4.0, 4.0 and 4.0 g/kg, respectively.

Discussion

In this study, dietary Met levels affected the egg weight, egg mass, FCR, hatchability, proportion of healthy ducklings and their weight, but did not affect egg production and fertility. Previously, Xiao *et al.*⁽⁵⁾ found improvements in egg production, FCR, fertility and hatchability after increasing the Met level from 0.25 to 0.35% in Chinese broiler breeders, whereas Hosseini *et al.*⁽⁸⁾ showed that increasing the Met concentrations from 0.20 to 0.45% for 8 weeks during the peak laying period in Iranian broiler breeders impaired egg production, egg mass and FCR, but did not affect hatchability, quality of chicks or their weight. In the previous study of Longyan laying ducks from 19 to 47 weeks of age, improvements in egg weight were found after increasing Met level from 0.25 to 0.50%, but egg production, egg mass and FCR were not affected⁽⁷⁾. In contrast, in Shaoxing laying ducks, He *et al.*⁽⁶⁾ recorded improved egg production, egg weight, egg mass and FCR from increasing the Met concentration from 0.26 to 0.54% for 6 weeks during the late laying period. A similar improvement in egg production was obtained after doubling the amount of Met in the basal diets (0.26%) of Tsaiya laying ducks for 4 weeks⁽³¹⁾. Feeding laying hens diets containing 0.26% Met for 12 weeks starting from 34 weeks of age impaired egg production, egg weight, egg mass and FCR, but adding 0.10% Met normalised these effects⁽³⁾. In White Leghorn laying hens, Panda *et al.*⁽³²⁾ showed that egg production, egg weight, egg mass and FCR were not affected by increasing the Met level from 0.30 to 0.42% in different feed sources for 16 weeks during the peak laying period. Thus, previous studies using different bird ages, strains and/or Met concentrations in the basal diet varied in the responses to increasing dietary levels of Met. The Longyan breed used here is the prevalent duck laying breed in southern China and is of great consequence as more than 80 billion eggs are produced annually. Optimising nutrient provision for the layers and

 † Dietary Met requirement = the optimal dietary Met concentration (g/kg).

breeders is of economic importance, so the present findings are commercially relevant.

Albumen weight, albumen proportion and Haugh unit increased significantly, and the yolk proportion decreased with

increasing dietary Met in the present study; other indices of egg quality were unchanged. In Longyan laying ducks, egg SI, Haugh unit, yolk colour, yolk weight and eggshell weight did not change but the albumen weight increased, and thickness,

relative weight and strength of eggshell decreased by increasing dietary Met from 0.25 to 0.50%⁽⁷⁾. In Shaoxing laying ducks, the Haugh unit and yolk colour were not affected, but the albumen height and eggshell thickness increased after the Met levels changed from 0.26 to 0.54%⁽⁶⁾. Supplementing the diets of laying hens with various formulations of Met had inconsistent effects on the egg quality traits that were affected in the present study with Longyan breeders^(3,20,32). In the current study, increasing dietary Met led to linear increases in the albumen weight, together explaining the increase in egg weight and likely accounting for the weight of hatchlings⁽³³⁾.

Albumen (egg white) consists mainly (54%) of the major protein OVAL⁽³³⁾, lysozyme and ovotransferrin proteins. The expression of OVAL mRNA in the oviduct magnum (the main location for albumen secretion) increased linearly and quadratically as the Met concentration increased. To the best of our knowledge, this is the first report of enhanced expression of OVAL mRNA owing to increasing dietary Met in any avian species. In laying ducks, dietary Met supplementation increased the plasma levels of Met, lysine, arginine, isoleucine and histidine⁽⁶⁾, all of which are essential components of OVAL⁽³⁴⁾, which may explain why dietary Met enhanced the mRNA expression level of OVAL here. This finding may explain why increasing the Met level increased the albumen weight and hatchling weight because albumen has multiple physiological functions during different phases of embryo development⁽³⁵⁾. Exactly the same reasoning could explain the lowered hatchability of eggs from duck breeders fed low dietary Met (2.00 or 2.75 g/kg).

Ovarian-related indices⁽³⁶⁾ were measured to evaluate the effects of Met on development of the reproductive system. Dietary Met influences secretion of follicle-stimulating hormone and luteinising hormone, which stimulate the growth and development of follicles⁽⁴⁾. The weight of total LYF and the fraction of ovarian weight they accounted for were the only variables affected by dietary Met fed to the breeder ducks. The present results were consistent with the basal diet, with 2.00 g/kg, being deficient in Met for breeder ducks. Met-deficient diets in laying hens depressed protein synthesis in the liver (one function being to produce and export egg yolk proteins), magnum and other segments of the oviduct⁽³⁷⁾. Other effects of Met deficiency include a decrease in breast meat yield in broilers⁽⁹⁾ and influences on expression of genes related to protein turnover⁽¹¹⁾.

In the present study, dietary Met supplementation enhanced the hepatic levels of GSH, and activities of GPX and T-AOC, as well as the expression of *HO-1* and *Nrf2* genes in laying duck breeders. Supplemental Met reduced levels of MDA with a trend towards a quadratic effect, while not changing T-SOD activity or *SOD1* gene expression. The transcription factor *Nrf2* plays a crucial role in maintaining stable liver functioning by regulating the expression of antioxidants (*GPX*, *HO-1*, *CAT* and *SOD*)^(38,39). The *HO-1* has a crucial role in generating biliverdin and bilirubin, which are involved in the antioxidant defence system, and nutritional factors modulate *Nrf2* in order to increase antioxidant defences^(40,41). One previous study in young grass carp fish⁽⁴²⁾ investigated whether an adequate level of Met improved the antioxidant status by upregulating the

expression of *Nrf2* mRNA. Our previous study in Longyan laying ducks showed that increasing dietary Met from the 2.5 to 5.5 g/kg did not affect GSH, GPX or MDA in plasma⁽⁷⁾. In 16-week-old turkey hens, increasing Met from the levels recommended⁽⁴³⁾ had no effect on MDA, GPX and SOD activity in plasma or breast muscles, but hepatic levels of SOD and GSH declined and MDA increased significantly^(44,45). There are numerous studies in various avian species and types^(22,46–50) on effects of dietary Met at below and above recommended levels on antioxidant indices in laying duck breeders. As noted earlier, inconsistencies in results and differences to what has been observed here mainly reflect the differences in the animal models, Met deficiency level and tissue selected for evaluating the antioxidant status. In addition to the effects of graded dietary Met on the antioxidant status of breeders, and the effects measured on their eggs, some 'carry-over' effects were obvious on the hatchlings in the present study. For the most part, these were noted in brain rather than liver and included brain carbonylated protein. The effects of maternal dietary Met on the antioxidant variables measured in hatchlings did not exactly follow the effects noted earlier on maternal traits, nor the hatchability and proportion of healthy ducklings. Previous studies have investigated the effects of dietary Met on breeders, but they generally did not consider its effects on their offspring^(5,8). Indeed, only Brun *et al.*⁽⁵¹⁾ showed that maternal dietary Met affects the growth performance and lipid metabolism in the offspring of Muscovy duck breeders. Similarly, in sows fed a diet supplemented with Met in the form of DL-2-hydroxy-4-methylthiobutanoic acid, reductions in oxidative stress occurred in the intestines of their piglets⁽⁵²⁾.

The laying performance and reproductive performance of duck breeders are mainly concerns in duck industry. In the current study, the dietary Met levels for maximising the egg weight, albumen weight, egg mass and FCR were 4.6, 4.9, 4.4 and 4.8 g/kg, respectively. In addition, diet containing 4.0 g Met/kg could attain optimal hatchability, hepatic *GPX1* and *Nrf2* expression, and the hepatic GPX activity in duck breeders. These results indicate that dietary Met level at 4.0–5.0 g/feed is necessary in laying duck breeders. Previous studies used quadratic regression models as a fitted model with lower *P* values and higher *R*² values to evaluate nutritional requirements of poultry⁽⁵³⁾. Thus, the albumen weight and *Nrf2* mRNA expression level are supposed to be more reliable indicators for the evaluation of Met requirements of laying duck breeders.

In conclusion, the present study showed that the egg weight, albumen weight, egg mass, FCR, hatchability and 1-d duckling BW of laying ducks breeders were improved by increasing dietary Met to approximately 4.0–5.0 g/kg. The increases in the egg weight and albumen weight may have reflected up-regulated expression of OVAL in the oviduct magnum of breeders by increasing dietary Met. A diet containing 4.0 g Met/kg would achieve optimal hepatic *GPX1* and *Nrf2* expression, maximise the activity of GPX and minimise lipid peroxidation. There was an obvious carryover effect to the embryos as the maternal dietary Met enhanced *HO-1* and *Nrf2* transcripts and antioxidant status, and reduced carbonylated protein in the brain of hatchlings.
