Summary

Schistosomiasis remains to be the most common fibrotic disease resulting from inflammation and deposition of scar tissue around trapped parasitic eggs in the liver. Though chemotherapy eradicates matured worms efficiently and prevents the accumulation of schistosome eggs, fewer effective drugs are directed to reverse the present hepatic fibrosis. Therefore, treatment targeting hepatic fibrosis associated with schistosomiasis remains a challenging proposition. The present study was designed to investigate the potential complementary schistosomicidal and hepatoprotective activities of the methanol extract of *Capparis spinosa* L. (*C. spinosa*) with or without praziquantel (PZQ) and compare results with silymarin (Milk thistle), a known hepatoprotective and antifibrotic agent, on induced liver fibrosis by experimental *Schistosoma mansoni* (*S. mansoni*) infection. Total polyphenols in the extract were determined using colorimetric assay.

*C. spinosa* L. caused a partial decrease in worm burden; a statistically significant reduction in hepatic and intestinal tissue egg load, what was associated histopathologically with decreasing in both the number and diameter of granulomas, as well as restoring serum aminotransferases (AST & ALT), alkaline phosphatase (ALP) and improving liver albumin synthesis. The best results were obtained in the group of mice treated with *C. spinosa* L. and PZQ together. Quantitative estimation of total polyphenols content using colorimetric assay showed that *C. spinosa* L. leaves contain higher concentration of polyphenolic compounds than fruits.

It was concluded that *C. spinosa* L. has a promising hepatoprotective and antifibrotic properties and could be introduced as a safe and effective therapeutic tool with PZQ in the treatment of schistosomal liver fibrosis. Nevertheless further studies on the mechanism of action of *C. spinosa* L. in chronic liver diseases may shed light on developing therapeutic methods in clinical practice.

Keywords: *Schistosoma mansoni*; *Capparis spinosa* L.; praziquantel; silymarin; hepatoprotective; colorimetric assay

Introduction

Schistosomiasis produced by *S. mansoni* continues to be an essential cause of parasitic morbidity and mortality worldwide and is the most common fibrotic disease due to inflammation and the deposition of scar tissue around parasitic eggs trapped in the liver (Burke *et al*., 2010). This disease is the second most important tropical disease after malaria and has significant impact on public health and socioeconomic problems in developing countries. (Abdel Aziz *et al*., 2011).
It is known that fibrosis may be reversible while cirrhosis is an irreversible pathological process. Therefore it is important to prevent the progression of fibrosis to cirrhosis. However, there is no effective anti-fibrotic drug to date and the efficacy of most treatments were not conclusive in clinical trials (Bataller & Brenner, 2005). Currently available treatment for many liver diseases is ineffective and is associated with many adverse effects, usually resulting in liver transplantation as the only choice of treatment. Novel compounds which prevent or halt scarring response are urgently needed to prevent the progression to end-stage liver disease (Albanis et al., 2003).

Praziquantel (PZQ), as a safe anti-schistosomal drug, has been used for more than 30 years (Fenwick et al., 2003). In general, specific treatment of schistosomiasis results in parasite elimination, and later on, a slight reduction in hepatic fibrosis that is attributed to parasite eradication (Homeida et al., 1991). However, loss of PZQ efficacy in schistosomiasis treatment was reported from Egypt, where the drug was being used aggressively (Ali, 2011). Returning to nature was one of the suggested solutions for treatment of liver damage resulting from schistosomiasis. Referring to traditional medicine it was found that C. spinosa L. (Caper) a wild plant growing in Egyptian deserts was used by the Ancient Egyptians in the treatment of liver diseases (Tilli et al., 2011). Several claims about the usefulness of C. spinosa and its low toxicity were justified by experimental evidences. It was known by its anthelmintic activity in traditional Arab medicine and used to treat liver dysfunction. In Ayurvedic medicine capers are recorded as hepatic stimulants and protectors, thus improving liver function (Sher & Alyemeni, 2010). Its hepatoprotective, antiamoebic, chondroprotective, (Sher & Alyemeni, 2010), cardiovascu-
lar, hypolipidemic, antiallergic (Manikandaselvi et al., 2016) and antineoplastic activities (Gadgoli & Mishra, 1999; Satyanarayana et al., 2009; Bigoniya et al., 2013) have been reported. The clear filtrate was freeze dried (El-Hawary et al., 2015).

Material and Methods

Plant material

Leaves and fruits of C. spinosa L. were collected from Agiba in Marsa Matroh, Egypt, May 2016. Identification of the plants was kindly confirmed by Mrs. Threase Labib, senior botanist of plant taxonomy at El-Orman botanical garden, Cairo, Egypt. Voucher specimens No. (362014) has been deposited in the herbarium of Faculty of Pharmacy, Cairo University.

Preparation of methanol extract

A sample of C. spinosa L. leaves were separately air dried in the shade, powdered and kept in tightly closed amber colored glass container. 100 gm of dried leaves was extracted in methanol, then sonicated for 1 hour in an ultrasound bath, kept overnight and then filtered. The clear filtrate was freeze dried (El-Hawary et al., 2015).

Quantitative estimation of total polyphenols using colorimetric assay

Assay of total polyphenols was done using UV-visible spectrophotometer, Nicolet evolution 100 (Thermo) was used for recording UV spectra and measuring the absorbance in UV range. Establishment of the calibration curve and sample preparation

A calibration curve was prepared using gallic acid as a standard at concentrations of 5, 10, 20, 30, 40, 50, 60, 70, 80, and 90 μg/ml in methanol. Powdered air-dried samples of both leaves and fruit of C. spinosa L. were separately extracted, till exhaustion, with methanol. The solvent was evaporated to dryness. Stock solution (25 mg % in methanol) of leaves and fruits extracts were prepared. The method adopted was based on measuring the intensity of the blue color developed when phenolic compounds make a complex with Folin-Ciocalteau reagent using gallic acid as a standard. The concentration of the total phenolics was calculated as gallic acid equivalent (GAE) with reference to a pre-established standard calibration curve. Folin-Ciocalteau reagent (100 μl) was added to a test tube containing 20 μl of the extract solution. The contents were mixed, and a saturated aqueous sodium carbonate solution (200 μl) was added. The volume was adjusted to 2 ml by the addition of 0.68 ml of milliQ water and the contents were mixed.
vigorously and measured at 760 nm according to the method of Farag et al. (2014). For each concentration, three determinations were carried out and the average of the obtained absorbance was plotted versus the concentrations.

Experimental animals and infection
Laboratory-bred male, Swiss albino mice of CD-1 strain, each weighing between 18 – 20 grams were used in this study. Mice were maintained throughout the study in conditioned rooms at 21 °C and food with 24 % protein content. The animal experiment was carried out according to the internationally valid guidelines and the protocol of this study was approved by a scientific research ethics committee at the TBRI. The animal experiments were performed in accordance with the TBRI committee for laboratory animals' research guidelines [Schistosome Biological Supply Program (SBSP), Theodor Bilharz Research Institute (TBRI), Giza, Egypt]. Virulent Egyptian strain of S. mansoni cercariae were obtained from infected Biomphalaria alexandria snails, which were reared and maintained at SBSP, TBRI. Each mouse in infected groups was infected by subcutaneous injection with (60 ± 10) S. mansoni cercariae (Liang et al., 1987).

Drugs
Silymarin (Legalon®) purchased from (Chemical Industries Development (CID), Giza, Egypt under License of: Madaus GmbH, Germany) was given orally in a dose of 750 mg/kg/day (El-Lakkany et al., 2012) for 5 days/week for 8 weeks in the form of aqueous suspension in 2 % Cremophor EL (Sigma Chemical Co., St. Louis, MO, USA). Praziquantel ® (Praziquantel-Sedico Pharmaceutical Co. 6th of October City, Egypt) was given orally in a total dose of 1000 mg/kg divided equally on two consecutive days (Gonnert & Andrews, 1977) during the 6th week post infection (PI), in the form of aqueous suspension in 2 % Cremophor EL. C. spinosa L. methanol extract was given orally in a dose of 100 mg/kg/day (Satyanarayana et al., 2009) for 5 days/week for 8 weeks in the form of aqueous suspension in 2 % Cremophor EL.

Experimental design
A batch of 60 male Swiss albino mice was infected and divided into 6 groups (I-VI) and one group was uninfected (VII; served as normal control) as follows:

*Significantly different from infected (vehicle) group at P < 0.001.
All mice were sacrificed 8 weeks from day zero experiment by decapitation. After decapitation, blood samples collected in centrifuge tubes were centrifuged at 3000 rpm for 20 min. Serum was stored at -20 °C until used for biochemical assays. Porto-mesenteric perfusion was performed for recovery of S. mansoni worms in infected mice for subsequent counting (Duvall & De Witte, 1967). Pieces of intestine and liver were digested in 5 % KOH (potassium hydroxide) solution and number of eggs per gram intestine or liver was calculated to determine the ova count in tissue (Cheever, 1968). The percentage of different egg developmental stages (Oogram pattern) were studied according to the method of Pellegrino et al. (1962) in which eggs at different stages of maturity were identified and counted.

**Assessment of toxicity and determination of LD₅₀**

A group of 18 adult (6 weeks old) normal male CD-1 Swiss albino mice weighing between 20 – 25 g were used to study the toxicity effect and to determine the LD₅₀ of C. spinosa extract. They were subdivided into six subgroups of three mice each. Subgroups were treated orally with increasing doses of 100, 500, 1000, 2000, 3000 and 4000 mg/kg plant extract re-suspended in 2 % Cremophore EL (Sigma/Aldrich Chemical Co., St. Louis MO, USA). Mortality rates were recorded 24 hours post treatment. The death rate was used to judge toxicity.

**Assessment of biochemical parameters**

The Biodiagnostic kits at Dokki laboratory (Giza, Egypt) were used for the determination of serum aminotransferase enzymes (AST and ALT) activities, ALP and serum albumin.

**Histopathology and Granuloma Measurement**

Livers recovered from mice were fixed in 10 % buffered formalin.

and processed to paraffin blocks. Sections (4 μm thick) were cut 250 μm away from the preceding sections to avoid measurement of the same granuloma. Five paraffin liver sections were prepared from each animal and stained with haematoxylin and eosin (H&E) and Masson trichrome stains. Measurements of the granuloma size were conducted on non-contiguous granulomas, each containing a single egg (with intact or degenerated miracidia), using an ocular micrometer. The mean diameter of each granuloma was calculated by measuring two diameters of the lesion at right angles to each other (Von Lichtenberg, 1962). For each mouse, 40 granulomas were measured and associated hepatic histopathological changes were studied.

**Statistical Analysis of Data**

Data were reported as mean counts ± standard deviation. Statistical analyses were done using computerized statistical software program IBM SPSS 19.0. The independent sample t-test was used to assess the statistical significance of the difference between two study group means. Statistical significance was defined as \( P < 0.05 \).

**Results**

Results of quantitative estimation of polyphenols content using colorimetric assay

The absorbance of different concentrations of standard gallic acid was illustrated in Table 1. The present study revealed that *C. spinosa* L. leaves contain higher concentration of phenolic compounds (28.4 μg/ml) than fruits (7.3 μg/ml).

**Parasitological results**

Praziquantel resulted in the highest percentage of worm burden reduction (91 %) when administered alone to mice infected with *S. mansoni*. This percentage increased to (96 %) and (94 %) after the synergistic effect of silymarin and *C. spinosa* extract, respectively. Infected animal groups treated with praziquantel alone, praziquantel combined with *C. spinosa* extract and praziquantel combined with silymarin extract showed significantly different effects on worm burden when compared with infected group (i.e male worm, female worm, coupled worm and total worms, at \( P < 0.001 \)). Generally female worms were more affected by drugs used than male worms. They died when treated with praziquantel alone, or combined with *C. spinosa* extract and silymarin extract. Meanwhile the administration of *C. spinosa* extract alone or silymarin extract alone to the *S. mansoni* infected animals yielded in the lowest worm burden reduction, 14 % and 16 % respectively. The effect of *C. spinosa* L. and silymarin with/without praziquantel on the worm burden of mice infected with *S. mansoni* is shown in Table 2. All egg stages (immature, mature and dead) were observed in the intestines of infected non-treated and treated mice. As presented in Table 3, they were evidently affected by administration of praziquantel alone and showed a significant reduction in the percentage of dead ova (95 ± 1.30 %) when compared with groups administered with *C. spinosa* extract alone (14 ± 1.63 %) or silymarin extract alone (9.5 ± 2.12 %).

Administration of praziquantel alone to mice infected with *S. mansoni* showed the highest percentage in reduction of ova (80, 97 %), what was followed by *C. spinosa* extract alone (45, 62 %) and silymarin extract alone (34, 30 %) in both liver and intestinal tissues, respectively. The reduction percentage of ova count increased to 100 % in intestinal tissues after administration of praziquantel combined with *C. spinosa* extract or praziquantel combined with silymarin extract. Also, this reduction percentage in ova count was observed in hepatic tissues when treated with both praziquantel and *C. spinosa* extract (96 %), or praziquantel and silymarin extract (98 %). These effects of *C. spinosa* L. and silymarin with/without praziquantel on tissue egg load in mice infected with *S. mansoni* are presented in Table 4.

**Acute Toxicity and Determination of LD50**

Zero mortality was observed 24 hours, as well as post treatment with increasing doses of *C. spinosa* extract starting from 100 mg/kg to 4000 mg/kg, LD50 >4000 mg/kg. That means that *C. spinosa* L. extract is safe at the treatment dose of 100 mg/kg.

**Biochemical Parameters Assessments**

Infection of mice with *S. mansoni* resulted in defective excretion and elevation of serum AST, ALT and ALP values due to livers damage. Also a serious decrease in serum albumin was observed. These results were significantly different from uninfected (vehicle) group. Administration of praziquantel, *C. spinosa* extract and silymarin extract either alone or in combination with praziquantel to the infected animals with *S. mansoni* showed an improvement in all liver functions which were significantly different when compared with infected (vehicle) group (\( P < 0.05 \)). Except liver albumin the Infected animal group treated with praziquantel alone showed slightly better improvement in all tested liver functions when compared with other groups treated with *C. spinosa* extract alone or silymarin extract alone. The best results of serum albumin level were obtained when praziquantel combined with *C. spinosa* extract (3.36 ± 0.04 gm/dl). This result was nearly the same of that of the uninfected animal group (3.47 ± 0.15 gm/dl), Table 5 summarizes all these results.

**Histopathological Study**

Stained liver sections with haematoxylin and eosin (H&E) and Masson’s trichrome (MT) of *S. mansoni* infected but not treated mice demonstrated that liver tissue was studded with granulomas, many granulomas were fused together with intact eggs, also ballooned hepatocytes were diffusely seen. Hepatic tissues of the infected mice treated with PZQ display moderate degree of improvement with presence of many granulomas, loose fibrous reaction, less inflammatory aggregates and vasculature showed congestion together with the focal necrotic area. Hepatic tissues of infected mice treated with *C. spinosa* L. display mild to moderate degree of improvement, most granulomas appeared with dead egg, less fi-
Fig. 1. Histopathological examination of haematoxylin and eosin stained liver sections (a) Infected control group demonstrating large fibrocellular granuloma surrounding one intact egg (arrow) and peripheral zone of inflammatory cells, (b) Infected mice treated with PZQ demonstrating granuloma with loose fibrotic reaction (arrow) and dead egg (arrow head), (c) Infected mice treated with *C. spinosa* L. extract demonstrating notable reduction in granuloma size, with loosening of the central fibrous area of granulomatous reaction (arrow) and dense inflammatory cellular response (arrow head), (d) Infected mice treated with *C. spinosa* L. extract and PZQ demonstrating moderate loose of fibrotic reaction (arrow), dead egg (arrow head) and less cellular inflammatory infiltrate around (short arrow), (e) Infected mice treated with silymarin demonstrating compact granuloma with dense fibrotic reaction (arrow), intact egg (arrow head) and inflammatory area (double arrow), (f) Infected mice treated with silymarin and PZQ focusing on granuloma with dead egg (arrow), loose inflammatory infiltration (double arrow), hepatocyte with vacuolated cytoplasm (arrow head) (x: 400).
Fig. 2. Histopathological examination of liver sections from (a) Infected control group demonstrating granuloma with compact fibrous reaction (arrow) intact egg (arrow head) and moderate inflammation, (b) Infected mice treated with PZQ demonstrating loose fibrous area and mild degree of inflammatory reaction (arrow), (c) Infected mice treated with C. spinosa L. extract demonstrating granuloma with loose fibrosis, dead egg (arrow) and external layer of inflammatory cells (arrow head), (d) Infected mice treated with C. spinosa L. extract and PZQ demonstrating granuloma with loose fibrotic reaction and dead egg (arrow), (e) Infected mice treated with silymarin demonstrating granuloma with intact egg (arrow head) and compact surrounding granuloma, (f) Infected mice treated with silymarin and PZQ demonstrating loose of fibrous area around dead egg and less inflammatory reaction (arrow) [Masson’s Trichrome x: 400].
brosis, peri-inflamatory layers, and hepatocytes revealed moderate cytoplasmic vacuolation with vesicular nuclei or marginated chromatin. Hepatic tissues of infected mice treated with *C. spinosa* L. and PZQ revealed mild to moderate ameliorating impact, where many granuloma seen with loose reaction and dead eggs, a notable reduction in the number of granuloma and patchy areas of hepatic cells showed vacuolated cytoplasm. Silymarin alone has no effect on schistosoma granuloma, but the most effective impact was on hepatocytes where wide areas of intact hepatocytes were detected. However, ballooned hepatocytes in pericentral areas could be observed together with an increase in the extracellular matrix. Hepatic tissues of infected treated mice with PZQ and silymarin showed a notable reduction in the number of granulomas and hepatic cells showed loose mild vacuolated cytoplasm as shown on Figs. 1 and 2. The number and diameter of hepatic granulomas in different experimental groups are shown on Table 6.

### Discussion

Medicinal plants are used worldwide for centuries to promote and maintain health as well as to relief symptoms in chronic diseases. Polyphenols are phytochemical compounds found in plants which apparently have vital health benefits and prevent from health dangers such as cancer, high blood pressure, heart disease or diabetes (Rose, 2013). In general they are potent antioxidants, metal chelators with anti-inflammatory, antiallergic, hepatoprotective, antithrombotic, antiviral, and anticarcinogenic activities (Tapas et al., 2008).

In the present study, a quantitative estimation of total polyphenolic content using colorimetric assay revealed that *C. spinosa* L. leaves contain higher concentration of polyphenols than fruits, so the methanol extract of the leaves to estimate its biological activity was used.

### Table 5. Effect of *C. spinosa* L. and silymarine with/without praziquantel treatment on liver function tests 8 weeks post *S. mansoni* mice infection.

These results matched with the studies carried out by Yu et al. (2006) who isolated some phenolic compounds from the fruit of C. spinosa L. by chromatographic methods. Also Kulisic-Bilusic et al. (2012) evaluated the aqueous infusion of caper and showed an interesting compositional pattern containing several phenolic compounds reflecting the potential benefits of the plant. In this study, the evaluation of parasitological parameters was done to confirm that all mice had received unbiased S. mansoni infection. In addition the presence of hepatic granulomas around trapped schistosome eggs affecting hepatic functions was examined to confirm the eradication of the worms and eggs by PZQ. Histopathological examinations of hepatic sections of sacrificed mice in all groups, by staining with haematoxylin and eosin and Masson’s trichrome stains, for detection of the histopathological changes and fibrosis degree were done to assess the cure rates and degree of liver tissue healing after the treatment. In this research, treatment of S. mansoni infected mice with PZQ resulted in a 91 % reduction in worm burden. This was accompanied with significant reduction in the hepatic and intestinal tissue egg load by 80 % and 70 %, respectively. There was also a significant increase in the percentage of dead eggs when compared with the infected untreated group. These results are consistent with several previous studies accomplished by Issa (2007); Abdel-Rahman (2009), El-Sisi et al. (2011) and El-Lakkany et al. (2012). The main justification for these results is that PZQ affects adult schistosomes directly. This leads to their contraction, paralyzation and subsequent shift from mesenteric to hepatic veins where they are finally damaged by the phagocytic cells. In addition, PZQ causes destruction of the worm tegument leading to the exposure of tegumental antigen, which becomes easily accessible to the parasites’ specific antibody (Fallon et al., 1995). Administration of PZQ showed a significant improvement in all hepatic functions and associated histopathology with a significant decrease in the number and diameter of granulomas. These findings are in agreement with El-Sisi et al. (2011) and El-Lakkany et al. (2012). Remarkably, treatment of S. mansoni infected mice with C. spinosa L. alone resulted in reduction in worm burden by 14 %, which was accompanied with a statistically significant reduction in hepatic tissue egg load by 45 % and a statistically significant reduction in intestinal tissue egg load by 62 % when compared to the infected untreated group. In addition, administration of C. spinosa L. resulted in some healing of hepatic granulomatous lesions what was supported parasitologically by partial increase in the percentage of dead ova and associated histopathology by decrease in diameter of granulomas, more ova degeneration and fewer inflammatory cells. This may be attributed to the anthelmintic, anti-inflammatory, antioxidant, antithrombinic, immunomodulatory, and antipathotopic activities of C. spinosa (Manikandaselvi et al., 2016). Thus, it is possible that C. spinosa L. eliminates the products of oxidative reactions and assists in the immune-mediated destruction of worms and eggs. PZQ is an active anti-schistosomal drug, against all forms of schistosomiasis (Ali, 2011). To stimulate further PZQ healing outcome, which could diminish liver fibrosis simultaneously with worm removal. it was recommended to develop a combination of PZQ and an antifibrotic drug in the treatment of murine schistosomiasis (Doenhoff et al., 2002). Co-administration of C. spinosa L. with PZQ also showed a statistically significant decrease in worm burden (96 %) and no viable eggs were present, associated with reduction in hepatic tissue egg load by 96 % and 100 %, respectively. The reduction of intestinal tissue egg load and better healing of hepatic granulomatous lesions indicates that the use of C. spinosa L. along with PZQ did not interfere or affect the antischistosomal effect of PZQ. The administration of C. spinosa L. either alone or in combination with praziquantel showed a statistically significant reduction in the elevated liver enzymes ALT, AST and ALP. This reduction in serum transaminases (AST and ALT) and ALP values reveals that C. spinosa L. has a hepatoprotective activity. These protective effects might be as a result of plasma membrane stabilization and preservation the structural integrity of cells as well as repair of hepatic tissue damage caused by S. mansoni infection. Also, there was a significant elevation of the level of serum albumin. Determination of enzyme levels, like serum AST and ALT is essential for the evaluation of liver damage by schistosomal infection (Ay & Mantawy, 2013 and Al-Sayed et al., 2014). Necrosis or membrane damage releases the enzymes into circulation; so, they can be measured in the serum. In agreement with the reports of Kadry et al. (2013) and Mahmoud & Elbessousy (2013), the raise of these enzymes in serum may be due to the hepatocytes damage caused by the parasite eggs toxins released into the circulation. In addition, Naik et al. (2011) reported that following schistosomal infection the hepatocyte membrane damage seems to be the prime culprit for the marked increase of the serum enzymes such as AST, ALT, and ALP. Also, hypo-albuminemia may be due to malabsorption resulting from damage of intestinal mucosa due to the extrusion of great numbers of eggs or could be due to diminished synthesis, which may result from parasitic injury to hepatic cells (Oliveira et al., 2009). This study concurred with the study performed by Satyanarayana et al. (2009) who studied the hepatoprotective effect of the alcohol extract of Capparis sepiaria Linn. Capparaceae stem against carbon tetrachloride (CCI,) -induced toxicity in albino rats. The rats were administrated daily pretreatment with an alcohol extract of C. sepiaria (100 mg/kg) and the standard silymarin (25 mg/kg) orally for 7 days. The toxicant used on 7th day was CCI4 at a dose of 1.25 ml/kg as 1:1 mixture with olive oil. The extract resulted in a significant (p<0.01) reduction of the elevated levels of aspartate transaminases (AST and ALT) total bilirubin and rise of the decreased total protein level when compared with the toxic control. El-Lakkany et al., (2012) studied the effect of silymarin on S. mansoni induced liver fibrosis. It was reported that silymarin has a favorable anti-inflammatory and anti-fibrotic activity. Its application caused a partial decrease in worm burden; hepatic tissue egg
load, reduced the elevated ALT, and when it was combined with PZQ treatment, a complete eradication of worms, eggs and relieved liver inflammation and fibrosis were observed. Regarding silymarin treatment, it was noticed that there was no significant difference between treatments with C. spinosa L. extract or silymarin alone or in combination with praziquantel. Silymarin promotes liver health through its anti-oxidant, anti-inflammatory, anti-proliferative, and immune-modulatory effects (Polyak et al., 2013).

The choice of PZQ and silymarin as suitable drugs for the treatment of schistosomiasis and liver fibrosis was matched with many previous studies. Rabia et al. (2010) proved that treatment with PZQ alone or combined with silymarin resulted in significant reduction of parasitological parameters where reduction in worm burden was associated with a reduction in tissue egg load and changes in the oogram pattern. These results were confirmed also by our study.

Numerous previous studies confirmed that phenolic compounds isolated from C. spinosa L. possess hepatoprotective activity. For example Gadgoli and Mishra (1999) isolated p-methoxybenzoic acid (Phenolic compound) from C. spinosa L. leaves. It possessed significant antihelminthic activity against carbontetrachloride and paracetamol induced hepatotoxicity in vivo and thioacetamide and galactosamine induced hepatotoxicity in isolated rat hepatocytes. Bigoniya et al. (2013) found that kaempferol (flavonoid) isolated form C. spinosa L. has a potent hepatoprotective action upon CCl4 induced oxidative stress and liver toxicity in rat. The hepatoprotective effect of kaempferol can be correlated with its efficiency to normalize the levels of serum marker enzymes and enhance the antioxidant defence status. The findings suggest that kaempferol can be used as a safe and effective alternative chemopreventive agent in the management of liver disorders.

In conclusion, C. spinosa L. leaves extract has a promising hepatoprotective and antifibrotic properties and this effect may be attributed to the relatively high contents of polyphenols. It could be introduced as a safe and effective therapeutic tool with PZQ in the treatment of schistosomal liver fibrosis. Further studies are clearly warranted to investigate the efficacy of higher doses and longer duration of treatment of C. spinosa L. leaves extract in this model of liver fibrosis, and thus establish their clinical applicability in patients with chronic liver diseases.
